

Multimodal Data in the Medical Domain

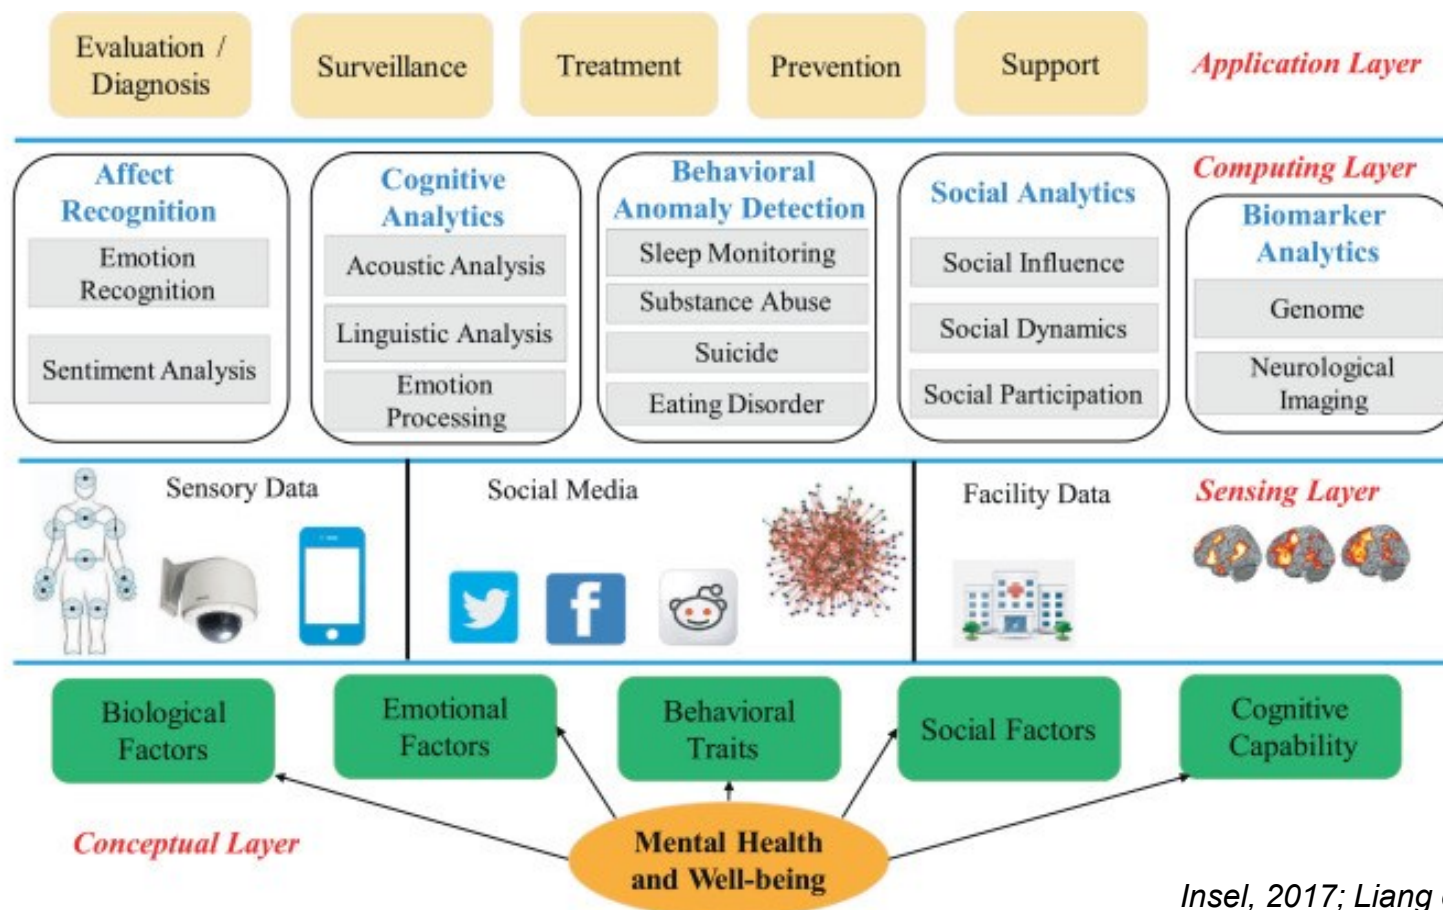

Dr Alexandra König, neuropsychologist
Email: alexandra.konig@inria.fr

Background...

- Clinical insights through keen behavioral observation & subjective questionnaires and scales
 - Punctual assessments based on interactions only
 - Variability in results, errors and misdiagnosis
-
- Need for diverse data and dimensional approaches as fundamental principles for better diagnosis of mental disorders
 - “measurement-based care” rather than relying only on clinical judgment
 - Shift from late disease management and cure to preventative-personalized precision medicine

Digital phenotyping

“moment-by-moment quantification of the individual-level human phenotype in situ using data from personal digital devices , especially smartphones and wearable sensors “

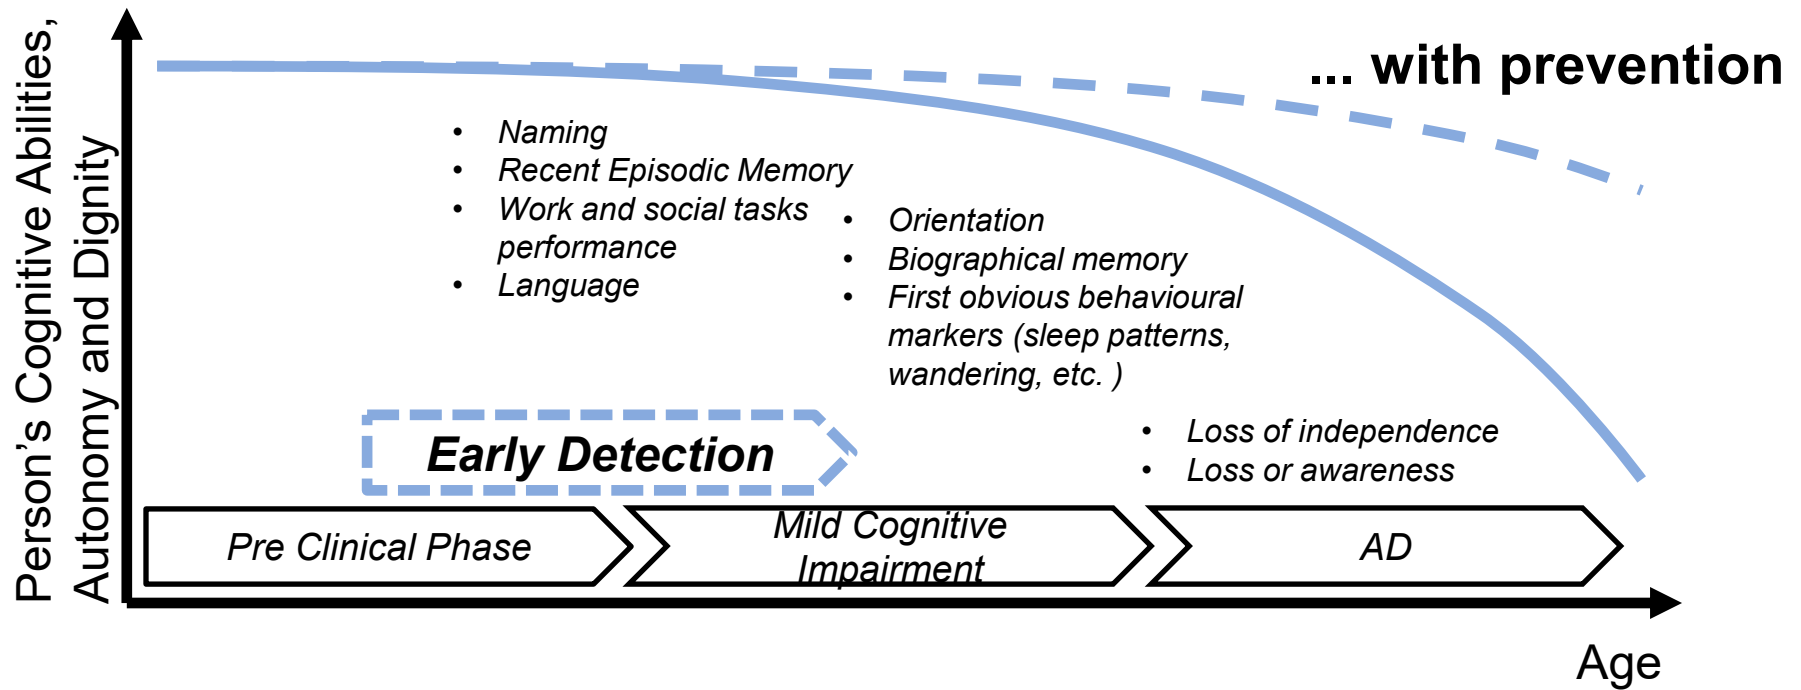

Insel, 2017; Liang et al., 2019.

Research project examples

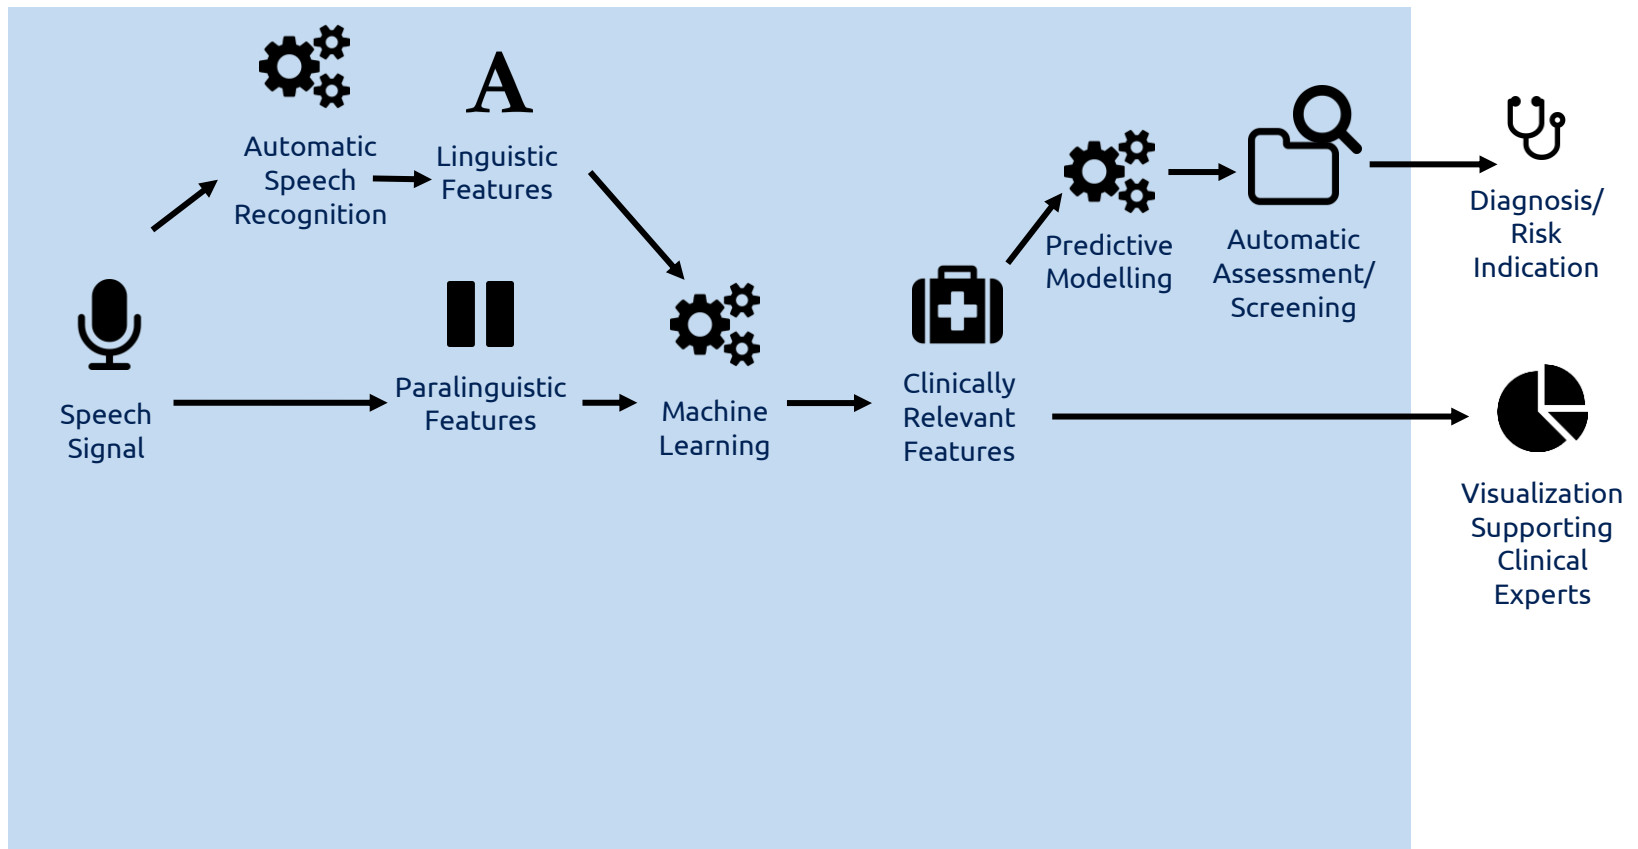

- Deep Speech Analysis for Cognitive Assessment in Clinical Trials (**DeepSpa**) / European Institute for Innovation & Technology (EIT) Health
- **Mephesto** - Digital Phenotyping 4 Psychiatric Disorders from Social Interaction/ Joint Program INRIA & DFKI

Neurodegenerative Diseases (Alzheimer's)

Speech Analysis platform

Use case 1: Telephone-based pre-screening

Need for:

- automatic
- inexpensive
- remote screening solutions

Recorded speech is analysed by:

- Linguistic
- Paralinguistic features

Battery of speech-based tasks

Subjects:

- Subjective CI
- Mild CI
- Dementia

Machine classification of clinically relevant features

Fully automated analysis of phone-based assessment is feasible for dementia screening

Classification results reveal good sensitivity

The word error in automated speech recognition is acceptable

DeepSpA Study: Longitudinal remote-monitoring of SCI

Maastricht University

120 participants, Age ~ 60, Subjective Cognitive Decline (SCI)

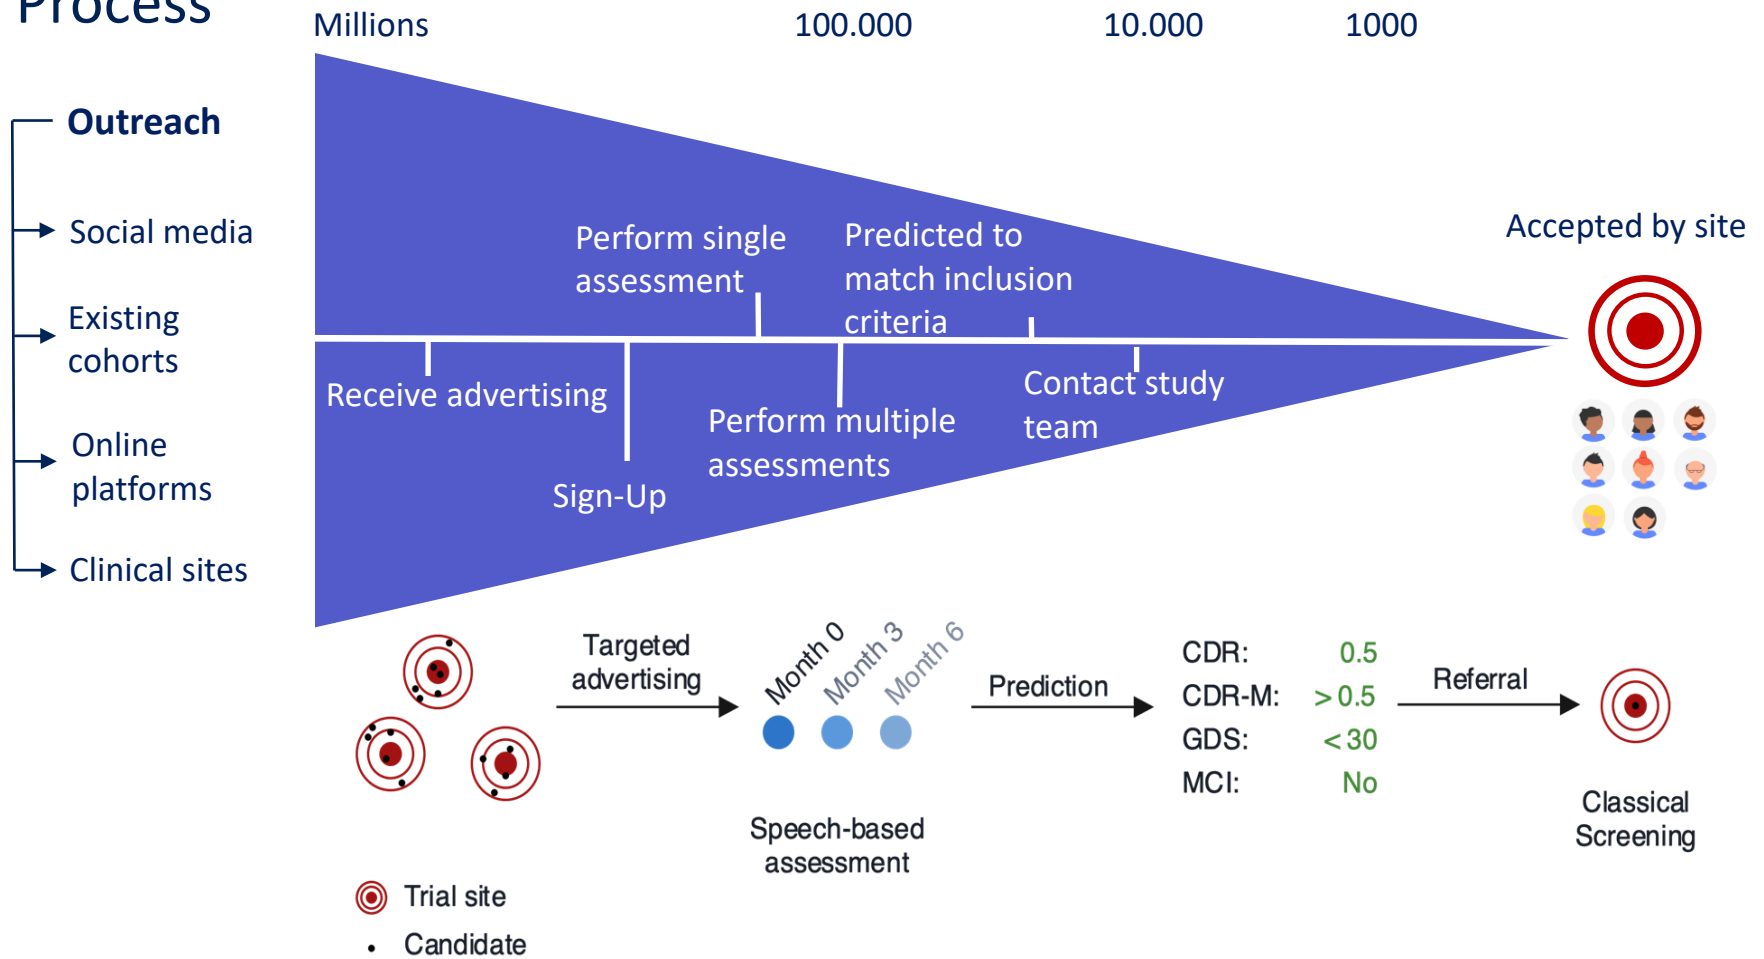

DeepSpA: Face2Face & Phone scores correlation

		Clinical				Baseline			M6	
		CDR SOB	CDR Tot	MMSE	IADL	Word count	Word count	Norm score	Word count	Norm score
Clinical	CDR SOB	1								
	CDR Tot	.74	1							
	MMSE	.49	.40	1						
	IADL	.72	.49	.39	1					
Baseline	Word count	.33	.30	.40	.39	1				
	Word count	.41	.32	.48	.44	.87	1			
	Norm score	.38	.29	.36	.37	.74	.86	1		
M6	Word count	.40	.22	.40	.30	.73	.50	.36	1	
	Norm score	.37	.33	.34	.19	.56	.23	.27	.88	1

-> high agreement between Face2Face and phone assessment

Process

Combining audio & video for behavioral analysis

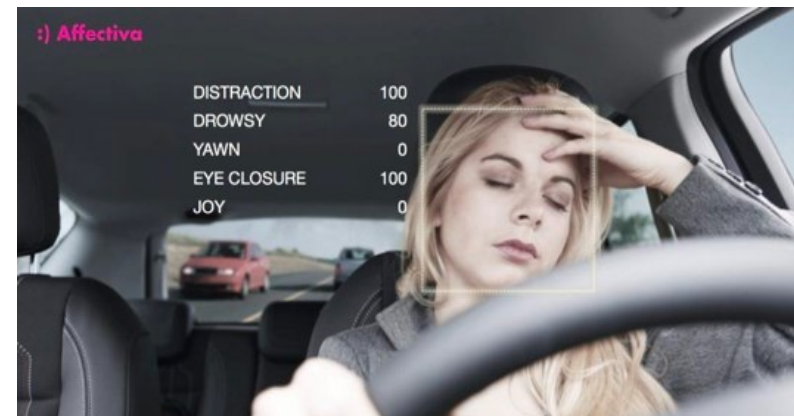

Automatic analysis of facial expression to capture :

- Emotional states/ Psychological symptoms
- Levels of engagement/levels of focus on task
- Weariness/Tiredness
- Control for cheating

- Specific face action unit abnormalities, mutual gaze and vowel space in speech

→ highly associated with depression severity
(Baker et al., 2016)

- Multimodal fusion of acoustic and visual measures better classification results (close to 90%) in accuracy than unimodal classification performance (Scherer, 2013)

Use case II: Remote cognitive monitoring via telemedicine in rural areas

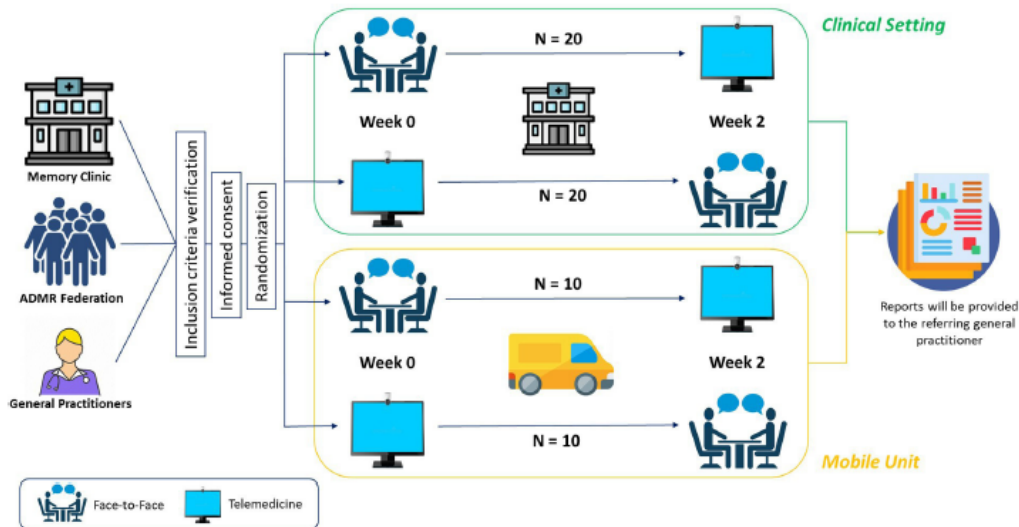

INRIA , City Digne-les-bains

60 participants, Age ~ 55

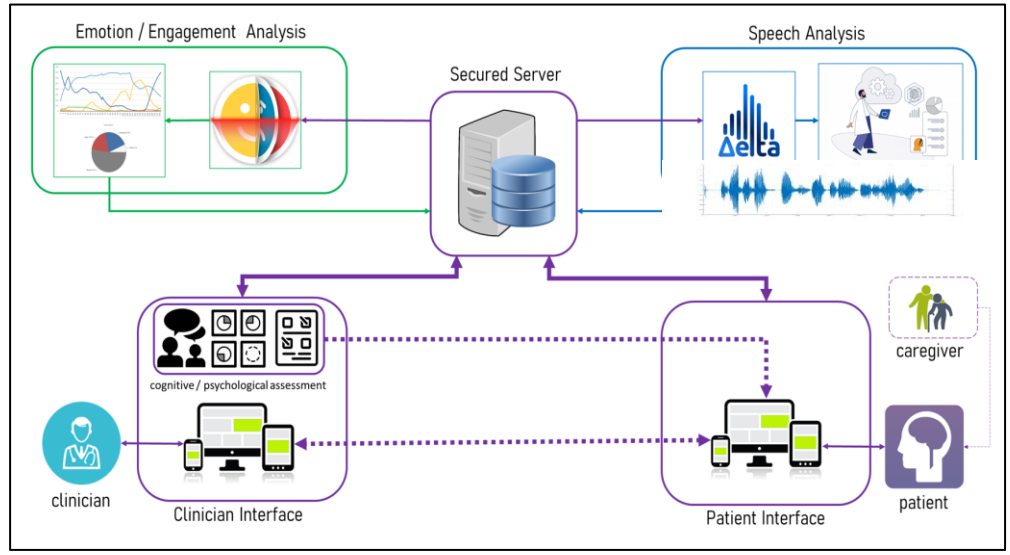

Interface

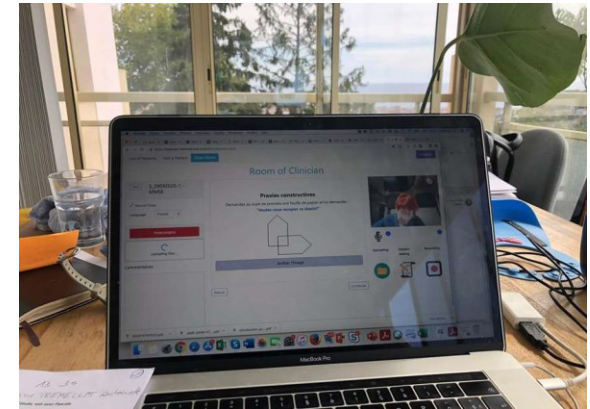

The interface displays a video analysis window with a French-speaking participant. It includes a 'FRENCH' language selection, 'Video Analysis' and 'Audio Analysis' checkboxes, and a 'Speech Analysis' section with various metrics like 'Durée sonore' and 'Ratios de la durée de son'. A 'Speech Analysis' graph shows a waveform, and an 'Emotion Analysis' pie chart shows engagement levels for A (31.5%), V (18.8%), E (3.1%), and H (7.0%).

Mobile Unit

Results & User feedback

Cognitive tests	N	TNP	FTF
MMSE ¹ , total score	50	26,42	28,24
FCSRT			
Total recall score	42	43,91	42,91
Delayed recall	42	15,16	15,07
Recognition score	41	15,70	15,69
Lexis, total score	46	56,74	58,34
Stroop			
Reading, duration(s)	42	54,10	59,22
Interference, duration (s)	40	153,44	152,52
SVF (z-score)	47	-0,33	0,34

2. Overall, the system is easy to use.

21 réponses

6. Which evaluation method do you prefer, face-to-face or by videoconference?

12 réponses

(19 responses)

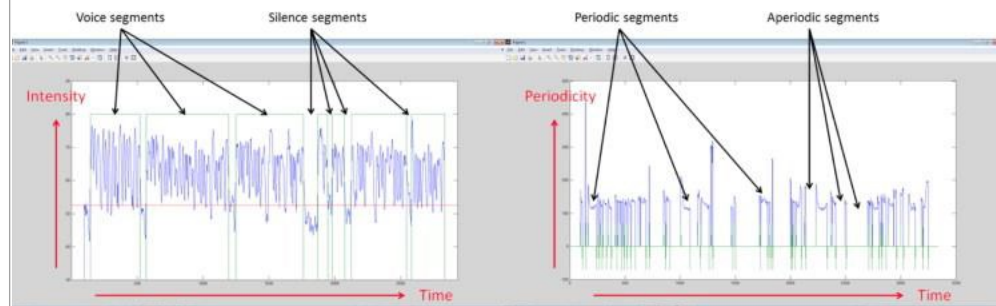

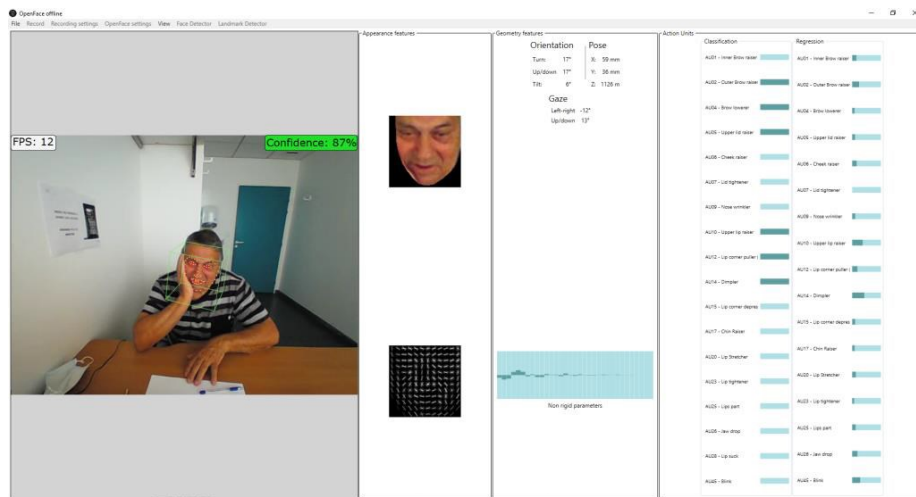

7 participants replied : both methods

„Strangely, I feel more free in front of the computer to express myself”
 “It still feels intimate and personal but this might depend on the clinician”
 “For me it is not different than face to face and I'm used to it.”
 “not rather pleasantly surprised, puts a distance that is rather facilitating”

Patient 1: “Although I was a bit nervous for the phone-testing (always when something new happens), it was convenient that the testing could take place at home. The instructions were clear (both content-wise and audio), but the test test-leader sounded as very-far away. I missed face-to-face contact, because now I had to get the cup of coffee myself.”

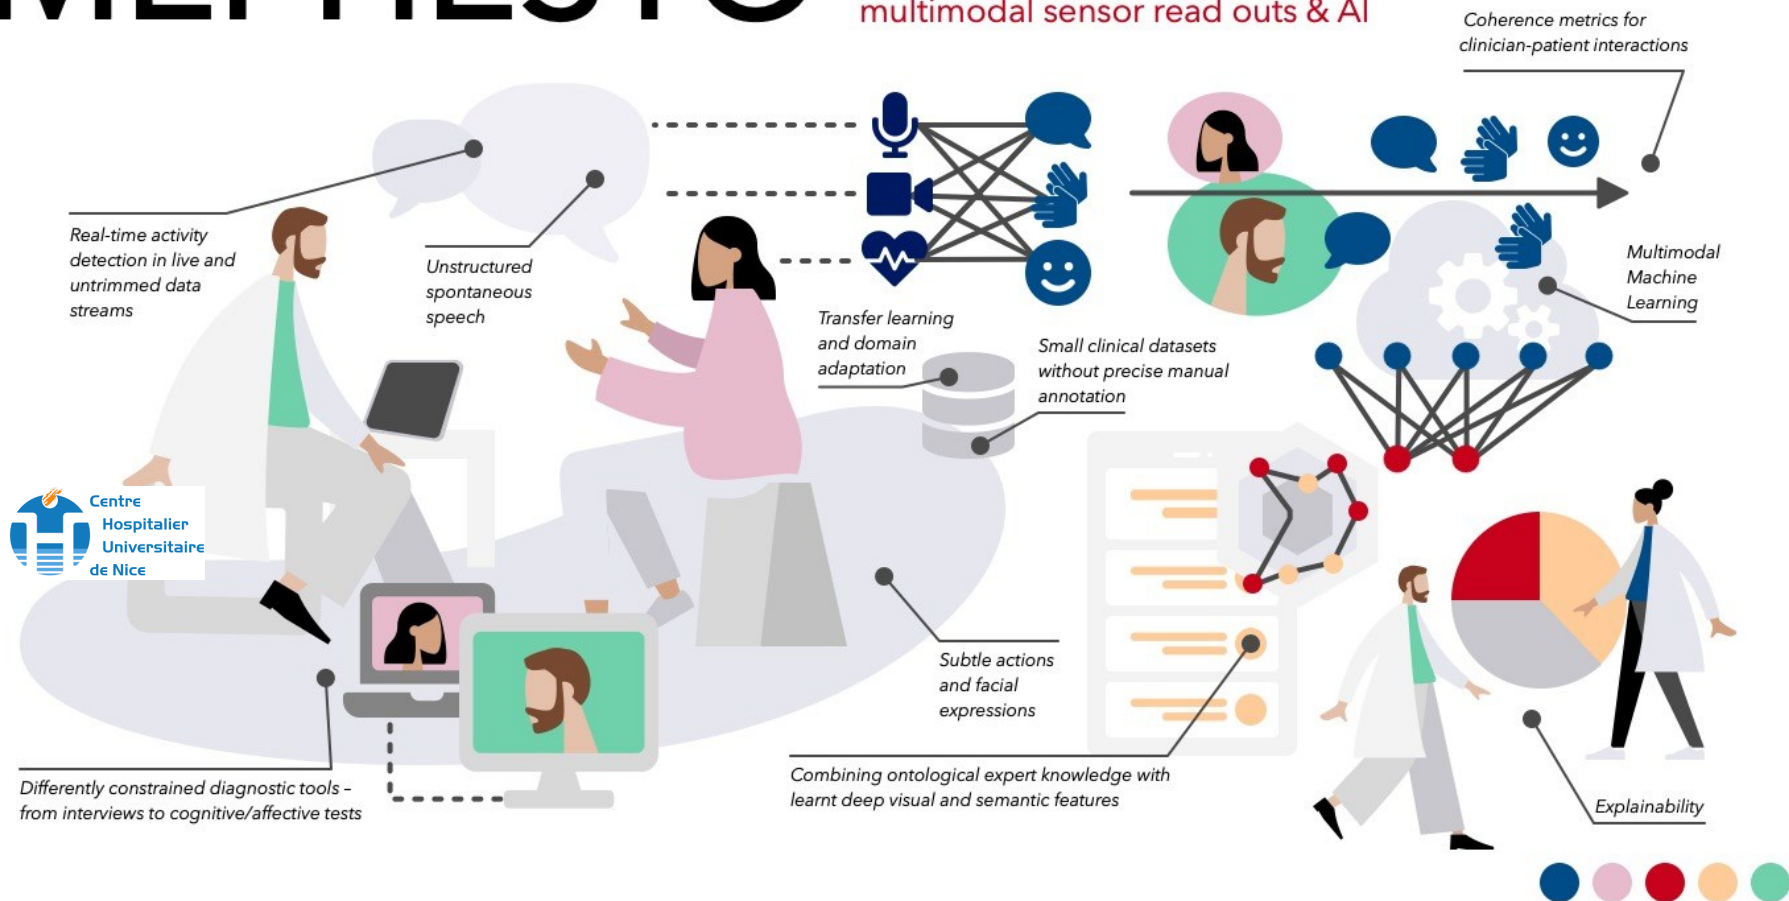

Future work

- Analysis of body behaviors (*facial expressions, head/gaze directions, gestures, postures,...*) to support assessments with **visual biomarkers** : emotions, engagement, fatigue, stress, level of concentration, focus
- Voice and **speech** analysis for new **biomarkers** to provide new insights on the patients' state and / or validate certain conclusions

Technical Set up at Pasteur

Mephesto study design

N= 150 (75 Major Depressive disorder / 75 Schizophrenia patients)

MEPHESTO

4 powerful clinical research cases
that lead the way

→ Create a longitudinal multimodal corpus of patient-clinician interactions within the context of psychiatric disorders

Use case A: Supporting differential diagnosis for major depressive episode etiology

Use case B: Quantifying therapeutic alliance by means of social synchrony

Use case C: Treatment outcome/Relapse prediction from negative symptoms in schizophrenia

Use case D: Robust and objective measurement of formal thought disorder in schizophrenia
